

Does the audit contrast separate the targeted intervention?

Paired target-minus-control differences in audit-local specificity · common templates and fixed comparison weights

Each point uses templates jointly complete for all eight principals, both positions and both contributing models. Invalid choices are never filled with zero. Colored tracks show conditional points/CIs; the separate gray tracks retain full-bank missingness bounds and robust intervals. All panels share an axis.

Only generated G enters the engineering criterion. Canonical likelihood argmax can differ from greedy decoding; normalized P weights confidence among canonical strings. Hollow markers / ! indicate failed validity or completeness. Neither ranks nor rank/46 are calibrated probabilities of a hidden preference.
